SPECIFICATION AMENDMENTS

1. On page 2, lines 2-13: please amend as indicated below using ~~strikethrough~~ and underline:

"Data communication systems have been under continual development for many years. One such type of communication system that has been of significant interest lately is a communication system that employs turbo codes. Another type of communication system that has also received interest is a communication system that employs LDPC (Low Density Parity Check) ~~code d~~ coded modulation. A primary directive in these areas of development has been to try continually to lower the error floor within a communication system. The ideal goal has been to try to reach Shannon's limit in a communication channel. Shannon's limit may be viewed as being the data rate to be used in a communication channel, having a particular SNR (Signal to Noise Ratio), that achieves error free transmission through the communication channel. In other words, the Shannon limit is the theoretical bound for channel capacity for a given modulation and code rate."

2. On page 30, lines 19 until p. 31, line 24: please amend as indicated below using ~~strikethrough~~ and underline:

"FIG. 17A ~~15A~~ is a diagram illustrating an embodiment of direct combining of LDPC (Low Density Parity Check) coding and modulation encoding. A binary sequence (e.g., a bit stream) is provided to an LDPC (Low Density Parity Check) encoder. The LDPC encoder introduces a degree of redundancy (or parity) within the bit sequence provided thereto. These LDPC coded bits are then provided to a S/P (Serial to Parallel) path such that the output symbols may be provided to a modulation encoder. This S/P path performs the bit to m-bit symbol transformation. The modulation encoder outputs a signal sequence that includes symbols (composed of LDPC coded bits) that correspond to a modulation having a constellation and a mapping.

FIG. 17B ~~15B~~ is a diagram illustrating an embodiment of BICM (Bit Interleaved Coded Modulation) that is employed in conjunction with LDPC (Low Density Parity Check) coding and modulation encoding. This embodiment is similar

to the embodiment described above that performs direct combining of LDPC coding and modulation encoding, with the exception that an interleaver is interposed between the LDPC encoder and the modulation encoder.

A binary sequence (e.g., a bit stream) is provided to an LDPC encoder. The LDPC encoder introduces a degree of redundancy (or parity) within the bit sequence provided thereto. These LDPC coded bits are then provided to an interleaver to generate a degree of randomness within the LDPC coded bits thereby (hopefully) making that LDPC coded bit sequence to be more robust to interference, noise, and other deleterious effects. This LDPC coded bit sequence that has been interleaved is then provided to a S/P (Serial to Parallel) path such that the output symbols may be provided to a modulation encoder. Again, this S/P path performs the bit to m-bit symbol transformation. The modulation encoder outputs a signal sequence that includes symbols (composed of the interleaved LDPC coded bits) that correspond to a modulation having a constellation and a mapping.

FIG. 17C ~~15C~~ is a diagram illustrating an embodiment of multilevel coded modulation encoding. Rather than require a S/P (Serial to Parallel) path between a single LDPC encoder and a modulation encoder, this embodiment shows a plurality of LDPC encoders operating in parallel such that the outputs of each of the LDPC encoder is already within parallel format (thereby obviating the need for the S/P (Serial to Parallel) path employed within the embodiments described above). The outputs of these LDPC encoders are provided to a modulation encoder. The modulation encoder outputs a signal sequence that includes symbols (composed of the LDPC coded bits provided by the various LDPC encoders) that correspond to a modulation having a constellation and a mapping."
